ABSTRACT:

This document provides users' information for a computer code, MOD-5, which calculates the time and energy dependent evolution of the neutron density in homogeneous media following initiation of a pulsed neutron source of arbitrary energy distribution. The code is based on a discrete stochastic model of the neutron slowing down process developed by the author. Copies of the code and associated computer software are available through the Argonne Code Center, Argonne National Laboratory, 9700 South Cass Avenue, Argonne, Illinois 60439.

Development of this computer code was supported in part by the Foundation Research Program at the Naval Postgraduate School.

TABLE OF CONTENTS

I. PROGRAM DESCRIPTION

Introduction

MOD-5 is a FORTRAN IV computer code utilizing a discrete stochastic model to obtain numberical solutions to the space independent neutron slowing down equation. The nucleus of the model is a "population vector" whose components are defined over a set of discrete energy states and specify the fraction of the total neutron population lying in a given state at a given time. The population vector may be advanced forward in discrete time steps by multiplication into a suitably designed one-step transition matrix. The method is rather similar to models devised by Perkel (1) and by Ohanian and Daitch (2) but has several unique features which greatly extend the capability of this approach.

Detailed discussions of the model may be found in two papers which have been included in this report (3,4) as Appendicies A and B, and the reader is urged to be thoroughly familiar with these before attempting to use MOD-5. Some useful information is also available in a doctoral dissertation based on this model (5), however many significant changes have been made since the dissertation was completed.

Specifics of the model will not be examined further here. This report is concerned only with providing technical information (a) about the structure and operation of the code, and (b) the mechanics of setting up typical problems for analysis by MOD-5.

Classes of Problems that May be Studied with MOD-5

MOD-5 evaluates numerical representation of time and energy dependent solutions of the slowing down equation following initiation of some sort of pulsed source. In its present configuration the following source conditions are available in MOD-5:

(a) Delta function in energy, delta function in time.

(b) Fission spectrum in energy, delta function in time.

(c) Arbitrary energy spectrum, delta function in time.

(d) Delta function in energy, uniform distribution over some small time interval.

A variety of functions and parameters are calculated by MOD-5. Among the more important are:

(a) Spectra (lethargy dependent neutron density) and energy moments at selected times following initiation of the source,

(b) Time dependent neutron density and slowing down density at selected energies and time moments of these densities,

(c) Time dependent distributions of times to capture, leakage, and first fission, and moments of these distributions,

(d) Steady state central core neutron flux and leakage flux in detail and group averaged form, and

(e) Miscellaneous parameters such as k_{eff}, capture probability, etc.

Organization of the Program

MOD-5 consists of a control program MAIN and 20 subroutines of

which all but one (GETIT) are called from MAIN. The flow of control is shown schematically in Figure 1 and a complete listing may be found in Appendix F. A description of the function of each subroutine may be found in Appendix E with elaborations in the comment cards included in the program listing.

All input data enters via READ (on cards) or GETIT (disk or tape files of cross sections). Subroutines STAWID through INCOND in the calling sequence are concerned with processing cross sections and other data do define state parameters, transfer coefficients $p_{i,j}$, and initialization of the state vector. GENTIM selects appropriate transition matrix generating times and operating time steps (δt and Δt respectively in Eqs. 44-46 of App. A). SQUARE and GENRAT work together in a DO loop to generate a stepping matrix defined for Δt. AMULT multiplies the population vector into the stepping matrix to produce a new population vector defined for a time one step later.

After AMULT is called MAIN performs a series of operations to determine the progress of the neutron density, and selects one of several paths in the control sequence. If the desired number of operating iterations (multiplications of the population vector into the transition matrix) has been completed, or if at least 99% of the population lies below the energy range of interest or in capture, fission or leakage states, the evolution of the population vector is terminated and control goes to a series of routines that process the data for output listing (NORMAL-OUTPUT). Otherwise the matrix is evaluated for one of three possibilities:

(a) If the real operating matrix does not lie at the bottom of the virtual operating matrix (See App. B and C for definitions of these terms) the real matrix is evaluated to see whether it should be moved downward in energy. This shift is performed if a fraction SCRIT of the total population has been slowed down below the lower energy boundary of the real matrix. In this event the new position and size of the matrix is determined and then control is transferred to statement 2 in MAIN.

(b) Next MAIN tests to see whether the operating time step should be doubled to compensate for decreasing collision rates as the population moves downward in energy. If it is to be doubled the matrix is squared by SQUARE. At this point new rows can be added to an incomplete matrix by GENRAT if the probability for a collision in Δt for each row ($v\Sigma_t \Delta t$) exceeds CRIT (DEFAULT value 0.001)

(c) If the matrix is not shifted downward in energy, control is finally returned to AMULT for another operating iteration on the population vector.

II. USERS INFORMATION

Restrictions on Complexity of the Problem

Almost all of the variables in MOD-5 have been included in a COMMON block. The list below reflects the restrictions imposed by the COMMON block that appears in the program listing in Appendix F. The program has been adapted to handle up to 701 virtual states and 201 real states in a problem with a single isotope simply by replacing the existing COMMON blocks with an appropriately modified form.

Max. number of isotopes	5
Max. number of real energy states	71
Max. number of virtual energy states	201
Max. number of broad groups for input cross sections	26
Max. number of time steps	400
Max. number of time moments	21
Max. number of groups from which inelastic scattering can take place	10

Running Time

On the IBM 360 the execution time in seconds is given approximately by the formula

$$t = 0.004\ N\ N_v + 10$$

where N is the number of real states and N_v is the number of virtual states

Basic Data Deck Format

The input data to MOD-5 requires a minimum of 6 data cards.

CARDS 1 - 3 Provide for a title block. FORMAT 18A4

CARD 4 A listing of initial values of the control variable L (Appendix D). Note that column 4 (L(2)) must always

have a "1" punch and column 24 (L(12)) must always have a "0" punch. FORMAT 30I2

CARD 5 — A listing of numbers locating the desired isotopes in the external cross section file. The isotopes may be listed in any order at input but will be rearranged by subroutine READ in order of increasing atomic mass (exception: hydrogen is always placed last in the list). FORMAT 5I5

(at this point in the program cross sections are retrieved from the disk or tape file)

CARDS 6 - n — NAMELIST NUMBRS. A list of the variables that can be read in under NUMBRS can be found in the listing of subroutine READ. DEFAULT values of these variables may be found in the Glossary (Appendix C) or in READ. Note that the position of values assigned to such variables as RHO, SCALE, (i.e. all variables for which one dimension specifies the isotope) must be determined by the order of the isotope numbers on CARD 5.

Cross Sections

MOD--5 has been provided with a library of the Russian 26 group cross section set (6). Cross sections, inelastic scattering transfer matrices, and 300°K resonance self shielding coefficients are included for the 40 isotopes and 3 fission fragment sets listed below. The cross sections presumably will be stored by the user on disk or tape and are retrieved by subroutine GETIT. The numbers below are used on CARD 5 to specify the desired cross section sets. Auxiliary program SLOAD (Appendix G) should be used to load the external files in the correct format.

1. hydrogen	15. potassium	29. lead
2. deuterium	16. calcium	30. bismuth
3. lithium-6	17. titanium	31. thorium-232
4. lithium-7	18. vanadium	32. U-233
5. beryllium	19. chromium	33. U-234
6. boron-10	20. iron	34. U-235
7. boron-11	21. nickel	35. U-236
8. carbon	22. copper	36. U-238
9. nitrogen	23. zirconium	37. Pu-239
10. oxygen	24. niobium	38. Pu-240
11. sodium	25. molybdenum	39. Pu-241
12. magnisium	26. tantalum	40. Pu-242
13. aluminum	27. tungsten	41. U-233 Fiss.Frags.
14. silicon	28. rhenium	42. U-235 Fiss.Frags.
		43. Pu-239 Fiss.Frags.

Sample Problems

Portions of the output listings for the following examples may be found in Appendix H.

```
EXAMPLE NUMBER 1
     EVALUATION OF ASYMPTOTIC SOLUTION TO SLOWING DOWN EQUATION.
     INFINITE HOMOGENEOUS MODERATOR.  DELTA SOURCE IN TIME AND ENERGY.

   (50)=1.00,SIGTE=26*4.7,SIGSB=26*0.,SIGNB=26*0.,SIGCB=26*0.,
   SIGTB=26*4.7,AMUB=26*0.05556,E=144*0.,FSS=3120*1.,&END
```

Comments:

CARD 4	L(3)=1	because N=NVIR (CARD 6)
	L(4)=1	because it is desired to study the time dependence of the neutron density at E(NM)
	L(6)=1	The state widths will be chosen to provide an optimal description of elastic scattering. See description of STAWID in App. F.
	L(7)=1	To compare calculated and theoretical time moments.
	L(8)=L(9)=0	Because L(11)=1
	L(11)=1	Delta function source
	L(12)=0	Required input value, this variable is redefined internally

	L(15)=1	A listing of the time dependent neutron density at EII(NM) and slowing down density at E(NM) will be printed in OUTPUT.
CARD 5	NOLIST(1)=8, NOLIST(2)=0,etc.	Cross sections for carbon will be retrieved from the external file. No other isotopes are present.
CARD 6	N=51	51 real states
	NVIR=51	51 virtual states
	NMO=8	8 time moments will be evaluated to orders listed in NMOM
	RHO=1.64	Nominal mass density of graphite (gm/cc)
	E(50)=1.00	Lowest energy of interest is 1.00 eV.
	SIGTB=26*4.7, etc	Cross sections from external files are replaced with an idealized set in which there is only elastic scattering and the cross section is independent of energy.

PERTINENT DEFAULT VALUES ASSUMED

NI=1	one isotope
NF=0	no fissionable isotopes
NSCAT=1	Stawid is called (because L(6)=1) and will optimize for scattering into one lower energy state.
MAXT=400	If necessary, the population vector can be evaluated for 400 time steps
CRIT=.001	Normally user will not need to override DEFAULT values of CRIT OPCRIT, SQCRIT, SCRIT and CONVC. The chosen values are based on operating experience.

```
EXAMPLE NUMBER 2
      STUDY OF SLOWING DOWN OF NEUTRONS FROM A 0.5 MICROSECOND, 2.46
      MEV PULSED SOURCE (0,0).  DEMONSTRATES TRAVELING ARRAY.
1 0 0 0 1 1 0 1 0 0 0 0 0 1 0 0 1
  8
NUMBRS NVIR=109,NSCAT=2,OPCRIT=0.5,SQCRIT=0.25,TIMWID=0.5E-06,RHO=1.64,
E(1)=2.46E 06,&END
```

Comments:

CARD 4	L(3)=0	because N<NVIR, the real transition matrix will follow the pulse as it moves downward in energy.

	L(4)=0	In this problem the evolution of the neutron distribution from the source is of special interest.
	L(9)=1	The source simulates a d(d,t)n pulsed source with a delta-function distribution in energy and a uniform 0.5 microsecond distribution in time (specified on CARD 6)
	L(11)=0	Complementary to L(9)=1
	L(18)=1	In addition to printing interpolated time distributions the program will print DENS and SDENS at every operating time step.
CARD 5		Same as Example 1
CARD 6	NSCAT=2	The distribution of neutrons following an elastic collision spans two lower energy states (optimized in STAWID)
	NVIR=109	With this many states the energy range 2.46 MeV to 1.0 eV is spanned.
	OPCRIT=0.50 SQCRIT=0.25	Increasing the values of these parameters increases the operating time step widths proportionately. In this problem MAXT=400 is not adequate to allow a run to completion unless OPCRIT and SQCRIT are increased.
	E(1)=2.46E 06	Since L(4) = 0, E(1) must be specified or a DEFAULT value of 10.5 MeV will be assigned.

The DEFAULT option for cross sections is to load from the external file.

```
EXAMPLE NUMBER 3
     STUDY OF SLOWING DOWN SPECTRA IN REPRESENTATIVE FAST MULTIPLY-
     ING ASSEMBLY.  FISSION SOURCE - DELTA FUNCTION IN TIME.
0 1 0 0 1 0 0 0 0 1 0 0 0 0 1
  34   36   20   13
&NUMBRS NVIR=121,NI=4,NF=2,EHI=2.622,3.016,.965,.848,BUCKLE=0.0072,
 DU(2)=119*0.05,SCALE=52*.1,26*.5,&END
```

This problem analyzes various time dependent processes in a fast multiplying system. Steady state properties are derived by integrations over time

CARD 4	L(4)=0	E(1) must be specified, in this case a DEFAULT value of 10.5 MeV will be used since no other value is specified in NUMBRS (10.5 MeV is the upper energy limit of the 26 group cross section set).
	L(6)=0	STAWID is not called. Should L(6)=1 STAWID would be called and the state structure would be optimized for the isotope of smallest mass (generally also of the greatest moderating power)
	L(8)=L(9)= L(11)=0	By DEFAULT a fission spectrum source, delta function in time, will be defined.
	L(12)=0	This will be redefined to L(12)=1 in subroutine XSECT because there are inelastic scattering isotopes present.
CARD 5		The first isotope on the input data set is number 34 in the external file (U-235), the second is number 36 (U-238), etc. READ will rearrange these in ascending numerical order.
CARDS 6-7	NI=4	Four isotopes in the system
	NF=2	Two of the isotopes are fissionable
	RHO(1)=2.622, 3.016,···	The density of U-235 is 2.622 gm/cc, of U-238 is 3.016 gm/cc, etc. These numbers appear in an order consistent with the list on CARD 5 and will also be rearranged by READ.
	BUCKLE=0.0072	Geometric buckling
	DU(2)=119*.05	Because STAWID is not called, the lethargy widths (or boundary values) must be specified for all states. IMPORTANT: For the user's convenience the lethargy at input is specified to log base 10 and then converted to base e internally. Thus the specification DU=0.05 provides 20 states per decase. Note that although the state widths are uniform in these examples they need not be in general. DU(1)=0 and DU(N)=1.E06 by DEFAULT always and need not be specified.

```
SCALE(1)=26*0.1,
26*0.1,26*0.5
```

The mean lethargy increment per elastic collision is less than the state widths for U-235, U-238 and iron. Scale factors of 0.1, 0.1, and 0.5, respectively, ensure that the energy distribution of scattered neutrons extends into the next lower energy state. For aluminum the DEFAULT scale factor of 1.0 is assumed.

Received April 24, 1970

The task of making detailed neutronics calculations for heavy moderating isotopes has always been a most difficult problem for a variety of reasons. Consider, for instance, the problem of calculating the time and energy (or lethargy) dependent neutron density $N(E,t)$ that develops in a homogeneous moderator during and following the introduction of a source, $S(E,t)$ in the MeV range. Monte Carlo techniques are very impractical because of the large number of collisions required per history. The usual multigroup stepping matrix techniques[1] are inapplicable for at least two reasons: (a) inordinately large matrices are required when collision energy losses are small and (b) scattering through the inelastic region may take but a microsecond while moderation to thermal energies may require times of the order of a millisecond, thus making it virtually impossible to choose a suitable time step upon which to define the matrix.

Analytical techniques[2,3] have been reasonably successful in predicting the low energy or asymptotic shape of $N(E,t)$ but they are incapable of dealing with the complexity of inelastic scattering, the effects of which carry over to relatively low energies.

We have been able to overcome many of these difficulties using our recently developed discrete stochastic model.[4] The model is similar in many respects to the usual time-dependent multigroup theory in which a multigroup neutron spectrum, represented here by a state vector $\bar{s}(t)$

$$\bar{s}(t) = [s_1(t), s_2(t), \ldots,] \tag{1}$$

is stepped forward in time by repeated multiplication into a stepping matrix $\bar{\bar{P}}_{\Delta t}$

$$\bar{s}(t + \Delta t) = \bar{s}(t) \cdot \bar{\bar{P}}_{\Delta t} \quad , \tag{2}$$

where the elements $P_{i,j}(\Delta t)$ of $\bar{\bar{P}}_{\Delta t}$ are probabilities for transition between groups i and j during the interval Δt, and $s_i(t)$ is the population of group i. The new model differs from multigroup theory in the method of calculating transition probabilities and in the use of a well-known result of the theory of Markov processes which allows the stepping interval to be conveniently increased

$$\bar{\bar{P}}_{n\Delta t} = (\bar{\bar{P}}_{\Delta t})^n \tag{3}$$

Equation (3) provides a mechanism for the generation of a stepping matrix with transition probabilities of consistent accuracy for any step and energy range.

A requirement for maximum accuracy in multigroup calculations of elastic scattering processes is that the groups be small enough to allow neutrons to scatter from the mean scattering energy in one group to the smallest energy of the next lower group. For moderating isotopes with mass $A \sim 200$ this requires at least 160 groups per decade in energy. Unfortunately, on most computers a stepping matrix of dimension 200×200 represents a practical upper limit (both in terms of computation time and storage requirements) while typical slowing down problems span four or more decades.

We have circumvented this restriction by allowing the stepping matrix to cover only that region of energy occupied by the neutron population at a given instant. It is a well-known result of collision theory[5] that with purely elastic scattering the asymptotic energy distribution of moderating neutrons is nearly Gaussian with a dispersion (relative standard deviation) no larger than

$$D = \left[\frac{\langle E^2\rangle - \langle E\rangle^2}{\langle E\rangle^2}\right]^{1/2} = \left(\frac{8}{3A_L}\right)^{1/2} \quad , \tag{4}$$

where A_L is the atomic mass of the lightest isotope present. As the neutron population moves downward in energy following a short burst from the source, we allow the matrix to move with it using the previously mentioned technique to generate new rows of transition probabilities at the bottom of the matrix, and to increase time steps as appropriate (Fig. 1). In the calculation described below, a real matrix of dimension 200×200 was carried down the diagonal of a "virtual" (elements not stored in computer) matrix of dimension 700×700.

To reduce calculation times we have used the fact that in the elastic scattering region, transition probabilities decrease geometrically along a row moving away from the diagonal. As a result, for almost any useful time step and any moderator with $A > 10$, the transition probability

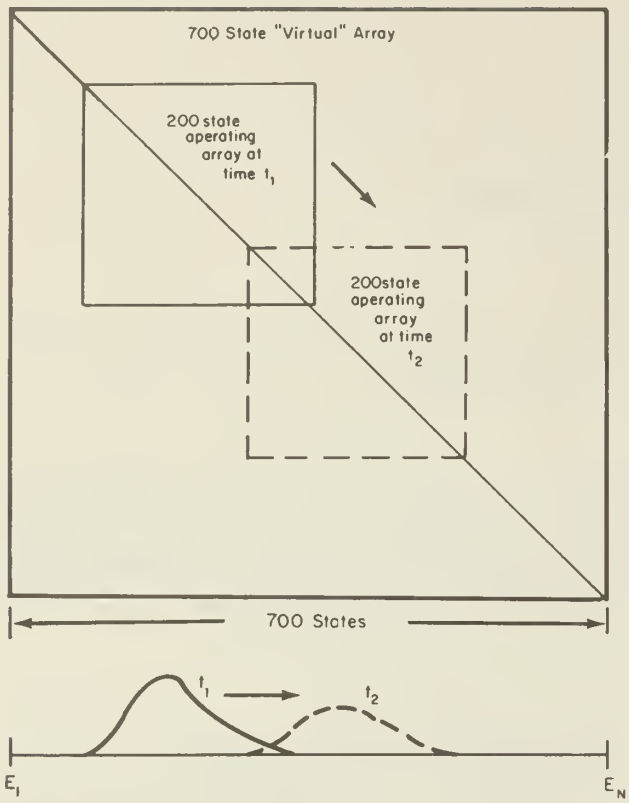

Fig. 1. Scheme for allowing transition matrix to follow neutron population.

$P_{i,j}(\Delta t)$ becomes vanishingly small (say $< 10^{-6}$) if $j > i + 10$. Thus, when calculations are being performed it is unnecessary to include transitions to a state j from any state i that is more than 10 states above j.

Application of our model does require two important compromises. The lesser of the two is the assumption of a normal mode space dependence. This is somewhat justified by the long mean-free-paths characteristic of heavy moderators. The more important compromise is made necessary because of the cooperative effect of inelastic scattering and time distributed sources in dispersing the neutron distribution. Inelastic scattering alone will cause neutrons from a 14 MeV source to be spread out to below 100 keV within a few nanoseconds. Once they are below the inelastic threshold the neutrons lose energy far more slowly and the narrow asymptotic shape is developed after a few collisions. However, because of the initial dispersal of neutrons over the broad inelastic region it is impossible to provide a matrix large enough to treat elastic scattering properly. Instead a few relatively broad groups must be used to span the energy region in which inelastic scattering reactions are the dominant moderating process. Within this region the elastic scattering kernel is adjusted by a scaling process that has been described elsewhere.[4] We have found that scaling tends to artificially disperse the energy distribution without significantly altering the mean energy. Since the inelastic kernel overwhelmingly dominates the shape of the distribution, scaling of elastic cross sections introduces only very minor errors.

As an example of the application of the model to heavy moderators we have chosen to study the lead slowing down spectrometer. Such devices have been in use for several years, in Russia,[3] in Germany,[6,7] and elsewhere. Lead spectrometers usually have a simple configuration such as a large lead cube resting on a concrete pedestal and penetrated by a 14 MeV pulsed neutron source and a small sample channel. If the source pulses are of short duration the neutrons will eventually develop a relatively narrow distribution in energy and the mean energy of the distribution can be easily related to elapsed time. By observing the time dependence of the emission of capture gammas from the sample being studied one can deduce the energy dependence of cross sections. Popov and others have made a number of studies of (n,γ) cross sections by this means.[8-11] More recently, there has been active study of temperature effects on the energy dependence of (n,γ) cross sections of various fast reactor materials.[7] Such studies are considered a necessary adjunct to the analysis of integral Doppler experiments and the theoretical analyses of uncertainties in nuclear data.

Two physical properties of a given spectrometer must be known before it is possible to extract cross sections from reaction rates and determine the accuracy of the estimates.

First it is necessary to know the mean energy of the neutrons as a function of the time elapsed from initiation of the neutron burst. It is easy to show that with a source that is a δ-function in time and velocity, and with a purely scattering medium of atomic mass A and scattering cross section Σ_s, the mean energy $\langle E(t) \rangle$ is given by[3,7]

$$\langle E(t) \rangle = \frac{M_N A^2}{2\Sigma_s^2} \frac{1}{\left(t + \frac{A}{v_0 \Sigma_s}\right)^2} , \qquad (5)$$

where v_0 is the source neutron velocity and M_N is the neutron mass. Although the above result is based on a highly idealized model, our calculations have shown that it works very well over the entire energy range below the inelastic threshold. With realistic source burst widths of up to 4 μsec the formula has been found to be satisfactory if t is replaced by elapsed time from mean emission time.

A far more difficult problem is posed by the desire to know something about the energy or lethargy distribution of the neutrons as time elapses. For most purposes it is sufficient to determine the relative standard deviation in energy (also commonly referred to as dispersion, or resolution) of $N(E,t)$ as a function of either the mean energy or the elapsed time. Clearly this parameter will determine the energy resolution of measured cross sections. Seufert and Stegemann[7] have concluded that for their Doppler measurements it is necessary that

$$\frac{\Gamma_\gamma}{\langle E \rangle} \ll \frac{\overline{D^s}}{\langle E \rangle} \ll D \ll | , \qquad (6)$$

where $\overline{D^s}$ is the mean level spacing, Γ_γ is the gamma width of the resonances, and D is the dispersion of the neutrons [Eq. (4)].

Our calculations have employed the 26-group ABN cross-section set[12] with an additional group added to cover the region from 10.5 to 14 MeV. The few resonances that occur in lead were ignored since they will not affect dispersion calculations significantly. The broad group cross sections were distributed over a fine group structure consisting of about 14 groups per decade above 300 keV and about 159 groups per decade below 300 keV. A geometric buckling of $B^2 = 0.000558$ corresponds to the physical dimensions of a large spectrometer (2.3 m on a side) but ignores such complications as the albedo of the concrete pedestal it sits on.

Output from the calculations consisted of (a) the neutron density in lethargy $N(u,t)$ and the relative standard deviation in energy and velocity at selected times following the initiation of the source, (b) time-dependent capture and leakage rates, and (c) steady-state flux.

The calculation was terminated when the neutrons reached 20 eV, at which point 75.7% had been lost to leakage, 12.2% had been captured in the lead and 12.1% were still slowing down.

Figure 2 displays the calculated lethargy-dependent neutron densities following source pulses of 0, 1, 2, and 4 μsec duration. Certain features of these figures are worth noting:

1. In Fig. 2a the structure and boundaries of the cross-section set are quite apparent. At 2 and 8 nsec the spectrum is almost completely determined by inelastic transfer from the source group.

2. In Figs. 2c and 2d a steady-state situation exists above 200 keV at the time the source is turned off.

3. A striking feature in all four cases is the rapidity with which a Gaussian shape is achieved by the population below 100 keV.

4. An estimate of the relative widths of the distributions at a given time is provided by the heights of the curves. Since the areas under the curves should be about the same at a given time (presuming the source is off) the width of the curve, or equivalently D, will vary inversely as the height. Thus at 50 μsec the distribution from a 4 μsec source is about 20% broader than that from a 1 μsec source.

A more complete description of the resolution of the pulses as a function of energy and elapsed time is given in Fig. 3. Here the abscissa is actually the ratio of D to its asymptotic value.

On the same figure we have plotted for comparison the

[12] L. P. ABAGYAN, N. O. BAZAZYANTS, I. I. BONDARENKO, and M. N. NIKOLAEV, *Group Constants for Nuclear Reactor Calculations*, Consultants Bureau, New York (1964).

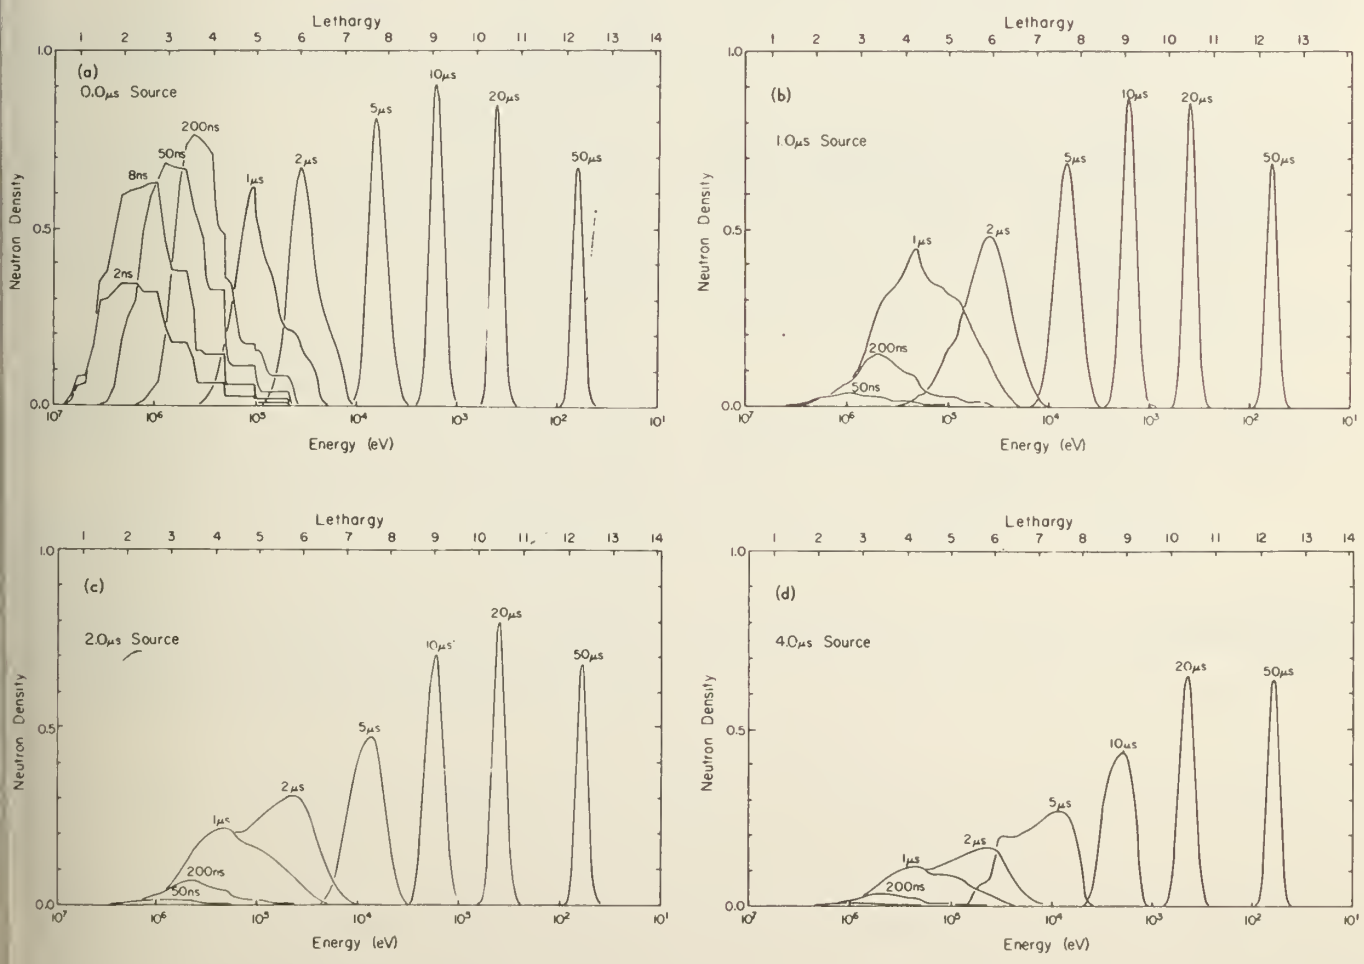

Fig. 2. The function $N(u,t)$ for source burst widths of 0, 1, 2, and 4 microseconds. Normalized to one source neutron at 14 MeV.

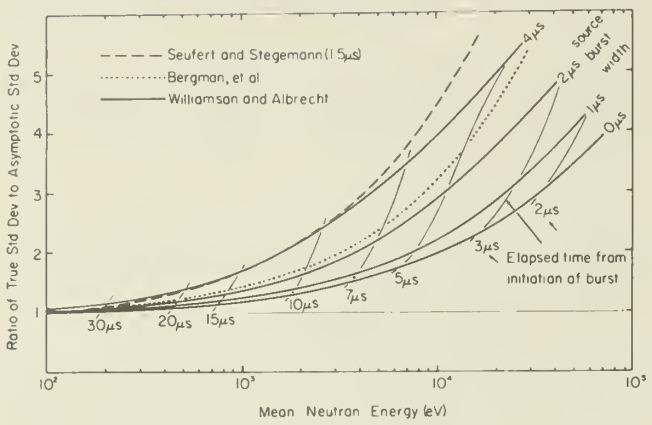

Fig. 3. Ratio of true to asymptotic value of relative standard deviation of $N(E,t)$ as a function of source burst width, mean energy, and time elapsed from initiation of source burst.

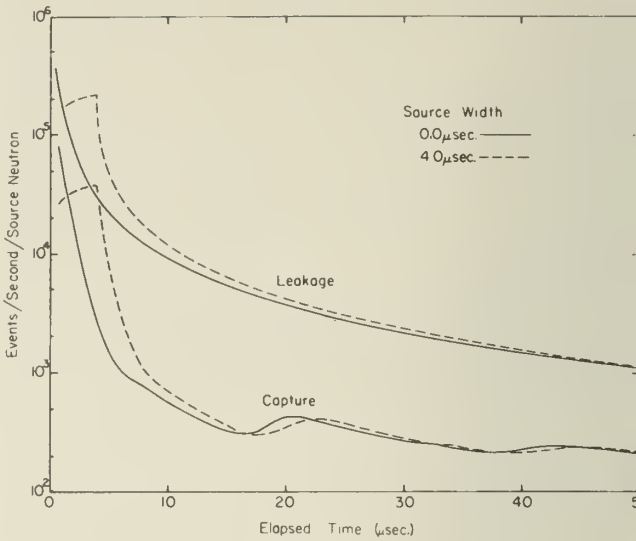

Fig. 4. Time dependence of leakage and capture for 0 and μsec sources.

prediction given by Bergmann et al.[3] (source time unspecified) and by Seufert for a 1.5 μsec source. Our results clearly provide a more optimistic estimate of the resolution of the spectrometer. Seufert's results are based on a model first proposed by Bergmann who suggested that the relative standard deviation in velocity ought to obey the following equation below 100 keV[a]:

$$\left[\frac{\langle v^2\rangle - \langle v\rangle^2}{\langle v\rangle^2}\right]^{1/2} = \left[\frac{2}{3A}\left(1 - \frac{\langle E\rangle}{E_0}\right) + D_0\frac{\langle E\rangle}{E_0}\right]^{1/2}, \qquad (7)$$

where $\langle E\rangle$ is the mean energy, E_0 = 100 keV and the constant D_0 was estimated to be ~0.3. The theoretical basis for this expression is obscure. In fact, in light of recently developed expressions for the lethargy dependence of velocity moments we would expect a better formulation to be a power series in $\left[\frac{\langle E\rangle}{E_0}\right]^{1/2}$.[13] As a useful approximation however, the following expression provides results that compare well with calculations:

$$\left[\frac{\langle v^2\rangle - \langle v\rangle^2}{\langle v\rangle^2}\right]^{1/2} = \left[\frac{2}{3A} + D_0\left(\frac{\langle E\rangle}{E_0}\right)^{0.84}\right]^{1/2}, \qquad (8$$

where, again, E_0 = 100 keV, but D_0 is ~0.07 for source widths of less than 1 μsec. The much smaller value of D is a consequence of the very rapid focusing of the distribution below the inelastic threshold, a fact that is certainly not intuitively obvious.

In practical applications of the spectrometer one of the overriding factors is the existence of background radiation mainly from capture gammas produced in the lead. In Fig. 4 the specific capture rate following 0 and 4 μsec bursts has been plotted. Consistent with reports of experimenters, a high background should persist for up to 5 μsec following the burst.

In closing, it should be noted that certain errors are inherent in the calculation and these are summarized below.

In a previous paper[4] it was shown that generally multigroup calculated dispersions will be larger than the true values. With the optimized stochastic model D is about 5% too large at all energies; however, this error cancels out almost completely in the ratios plotted in Fig. 3.

The leakage rates in Fig. 4 are probably pessimistically large early in the history of the pulse. This is because neutrons are actually born near the center of the cube rather than in a fundamental mode. Clearly a neutron born at the center has a smaller probability for leakage during its lifetime than one born elsewhere. Because of the overestimate of leakage we would expect that the distribution in Fig. 2 should properly have slightly greater amplitude.

[a] Our numerical calculations have shown that the following relation seems to hold true at all energies:

$$\frac{\langle v^2\rangle - \langle v\rangle^2}{\langle v\rangle^2} \Big/ \frac{2}{3A} = \frac{\langle E^2\rangle - \langle E\rangle^2}{\langle E\rangle^2} \Big/ \frac{8}{3A}.$$

The two quantities differ by no more than 5% above 100 keV and by less than 1% below 100 keV. So far, we have not obtained analytical verification of the result.

APPENDIX C

GLOSSARY OF FORTRAN VARIABLES USED IN MOD-5

Notes:

1. Numbers in parenthesis reference equations and Figures in the paper by Williamson and Albrecht (Appendix A).

2. If a variable does not appear in the common block the subroutine in which it does appear is given.

3. Jargon:

    a) Group - A broad energy group as defined by cross section sets such as ABN
    b) State - A fine "group" whose cross sections are typically drawn from the broad group set in which it lies.
    c) Operating Iteration - The process of multiplying the state vector into the one step transition matrix which is thus called the "operating matrix (array)"
    d) Generating Matrix - The matrix, typically defined for a very short time step, from which the operating matrix is derived by a sequence of squaring operations.
    e) Real Matrix - The matrix of transition probabilities stored in core
    f) Virtual Matrix - The actual matrix of transition probabilities this may be substantially larger than the Real Matrix but is not stored in core. For an explanation of the relationships between real and virtual matrices see the paper "Calculations of Neutron Time-Energy Distributions ..."

4. * Denotes variables which may be listed at input but for which default parameters have been defined in READ

5. ** Denotes variables which must be defined by the input data set and for which no meaningful default values are assigned.

6. *** Variables which must be updated if dimensions in the COMMON block are changed.

ACCUM	Total population outside real array
ALAM(k)	$N_{s,k}$ (Eq. A12)
ALP(k)	α'_k (Eq. 42)
ALPHA(k)	α_k
AMASS(k)**	A_k, atomic mass of isotope k
AMOM(i,j)	NMOM(i)-th time moment of distribution
AMU(i,m)*	Mean cosine of scattering angle for isotope m in state i (DEFAULT 0.0)
AMUB(k,m)	Group average cosine, group k, isotope m
ANUNOR(i)	Average neutron yield of fissions in state i
ATOM(2m-1,2m)	Name of isotope m
BGF(k)	Steady state fundamental mode flux in group k
BGSF(k)	Steady state leakage flux in group k
BUCKLE*	Buckling, B^2 (DEFAULT 0.0)
CAPT(n)	Neutron capture rate at time n
CCENER	Average fundamental mode energy in steady state
CONVC*	Convergence criteria for iterative calculation of optimized state widths in STAWID (DEFAULT 0.00001)
CORMOM(i,j)	NMOM(i)-th time moment corrected by extrapolation
CRIT*	Row generating criteria (45) (DEFAULT 0.001)
CSENER	Average energy of leakage spectrum neutrons
DB2(i)	Leakage cross section, DB^2, in state i
D32B(k)	Leakage cross section in group k

DDT	Generating time δt (46)
DE(i)	Energy width of state i, E(i-1) - E(i)
DEABN(k)	Energy width of group k
DENS(n)	Neutron density in state NVM at time n
DINT(n,j)	Interpolated time distribution at time n
DIST(n,j)	Raw time distribution at time n
DT(m)	Stepping time after m-1 squarings of the ones step matrix, $DT(m) = DT(1) \cdot 2^{m-1}$
DTI	Time step for interpolated distributions
DTIM(n)	Time step width at time n
DU(i)**	U(i-1) - U(i), Lethargy width of state i (DEFAULT DU(1)=0.0, DU(N)=1.0 E 06)
DUB(k)	Lethargy width of group k
DV(i)	V(i-1) - V(i), velocity width of state i
E(i)*	Lower energy limit of state i (DEFAULT E(1)=10.5 E 06)
EABN(k)	Lower energy limit of group k
EFFK	k_{eff} with extrapolation correction
EII(i)	$\langle 1/E \rangle_i^{-1}$ (A5, A7)
EMIN(m)	E^{min} for isotope m, redefined for each state
ERR(i,j)	Difference between exact and calculated values of NMOM(i)-th moment of density and slowing down density in state NVM
ESTK	k_{eff} estimated from fission distribution without truncation correction

EXM(i,j)	Exact value of NMOM(i)-th moment of density or slowing down density. Based on predictions of Eriksson (ref. 3) and Kosaly and Nemeth for asymtotic distributions in single isotope systems with constant cross sections.
FISS(n)	Fission rate at time n
FLCOR(i)	Correction factor for flux in state i
FLUX(i)	Neutron flux (fundamental mode) in state i
FVAR1,FVAR2, FVAR3,FVAR4	Free storage, not used in basic program
G(i)	Mean Collision rate per neutron in state i (γ_i in Eq. B6)
H(k,l,m)*	Probability that a neutron scattering from isotope m with initial energy in group k will end up in group l. (DEFAULT 0.0)
I,IA,IB,IC, ID, IE, IG,IH	General purpose indices
LEAK (n)	Leakage rate at time n
IND	n in Eq. 46
IPEAK	State number locating the peak of the neutron distribution
J,JJ	Do loop indices (unused in current version of MOD-5)
JROW	The number of rows in the matrix that have been defined
KROW	Number of the next row to be defined
L(j)**	Logical control variable (Appendix D)
LL	Temporary storage for NT

MAXR***	Maximum number of states in real matrix, including absorbing states (DEFAULT 74)
MAXT***	Maximum number of operating time steps allowed by dimensions in common block. (DEFAULT 400)
MAXV***	Maximum number of states in virtual matrix (including absorbing states)(DEFAULT 204)
N*	Number of energy states in real matrix, index of bottom energy state which is used to absorb all neutrons slowing down below lowest energy of interest (DEFAULT 71)
NC	An internally generated index for the external cross section file being read (READ, GET IT)
ND ***	Number of cross section sets that may be held in common (defined in READ, must be redefined if common block dimensions are changed. Value in existing program is ND=5)
NF*	Number of fissionable isotopes (DEFAULT 0)
NG(j)	Index of group to which state j (virtual index) belongs - if NG(j) = 0 state j straddles the boundary between two groups.
NGR***	Number of broad groups in cross section library (external file) (DEFAULT 26)
NI*	Number of isotopes in problem being executed (DEFAULT 1)
NII	Number of non-hydrogen isotopes (TRAN)
NIT	Number of time steps in interpolated output
NM	Number of active energy states in real matrix, NM = N - 1
NMO*	Number of time moments to be evaluated (DEFAULT 2)
NMOM(j)*	Listing of order of time moments to be evaluated (DEFAULT NMOM(1)=1, NMOM(2)=2)

NNG(k)	Index of lowest energy state lying completely within group k
NO	Index of external data set (cross sections) to be retrieved by GET IT
NOLIST(n)**	Index specifying the position of isotope n in the external data files. If NOLIST(1)=0 in primary data set (cards) the external data files (tape or disc) are not read.
NOMAX	Number of isotopes in external data file (tape or disc). This parameter is defined in READ (ftn) 14) and must be updated if the external data set is expanded or contracted.
NORM(i)	Normalization constant
NP1	N+1, Index of the absorbing state (real matrix) used for captured neutrons
NP2	N+2, Index of the absorbing state (real matrix) used for neutrons that have leaked from the system
NP3	N+3, Index of the absorbing state (real matrix) used for neutrons that have caused fission
NSCAT*	Used in connection with STAWID to define the number of lower energy states spanned by the distribution of scattered neutrons from a given state (Fig. 3) (DEFAULT 1)
NT	Maximum number of time steps allowed for problem in execution (must be ≤ MAXT)
NTIME	Running index of time
NTITLE	Number of words allocated in storage for the problem title block.
NTM	NT - 1
NTOP	The number of virtual states above real state 1,- The true state number of real state i is i + NTOP

NVIR*	Number of energy states in virtual matrix - index of absorbing state for neutrons that have slowed below the energy range of interest (DEFAULT 71)
NVM	NVIR-1
N2N(m)	Yield of (n,2n) reactions in group 1 for isotope m.
OPCRIT*	Operating criteria - ratio of first operating time step to mean collision time at peak of source distribution when the matrix is generated (DEFAULT 0.4)
P(i,j)	Transition probability matrix (10-15) - the lower triangular portion of this array is used for storage of transfer coefficients in transposed form ($P_{i,j}$ in Eq. 15)
POP(i,1),POP(i,2)	Population vectors at times n and n+1 respectively - Defined over the range of the real matrix
PTP(i)*	Population vector for the complete state set (Virtual matrix) - an accounting vector used to keep track of population lost when the real matrix is shifted down the state structure. (DEFAULT 0.0)
R(j)	For some state i, the probability of the occurrence of at least j-1 collisions before a neutron leaves the state, $r_{i,j}$ (24)
RHO(m)**	Mass density of isotope m
RHON(m)	Nuclear density of isotope m times 10^{-24}
RI(j)	Resonance self shielding correction factors, 1-fission, 2-capture, 3-total, 4-elastic
RR(i)	Average number of collisions before a neutron leaves state i (24)

RSD(j)	Relative standard deviation of time distributions (58)
RSDX(j)	Relative standard deviation of time distributions calculated from asymptotic formulae
RSDR(j)	Percent difference of computed relative standard deviation with respect to asymptotic value
RSS(i,j,l,m)*	Resonance self shielding coefficients (ABN) (DEFAULT 1.0) i = group index j = index defining value of σ_o 1 - 0 barns 2 - 1 barn 3 - 10 barns 4 - 100 barns 5 - 1000 barns 6 - ≥ 10000 barns l = index specifying cross section type 1 - fission 2 - capture 3 - total 4 - elastic m = isotope index
SARG(n)	Resonance self shielding parameter $\sigma_{t,n}$ on page 44 of ABN (Ref. 6)
SCALE(k,m)*	Scale factor for isotope m in group k (21,26) (DEFAULT 1.0)
SCRIT*	Criteria for determining the fraction of an existing neutron distribution that is bypassed when the real matrix is shifted downward in energy (DEFAULT 0.001)
SDENS(n)	Slowing down density at time n and energy E(NVM)
SFLUX(i)	Steady state leakage flux in state i
SIGC(i,m) SIGE(i,m) SIGF(i,m)	

SIGN(i,m)	Capture, elastic scattering, fission, and inelastic scattering cross sections for isotope m in state i (divided by SIGT(i) after XSECT)
SIGT(i),SIGTR(i)	Total and transport cross sections in state i
SIGCB(k,m)** SIGEB(k,m) SIGFB(k,m) SIGNB(k,m) SIGTB(k,m)	Capture, elastic scattering, fission, inelastic scattering and total cross sections for isotope m in group k
SIGEP(m)	First factor on right side of Eq. 36 - for isotope m
SIGTBT(k) SIGTRB(k)	Total and transport cross sections in group k
SQCRIT*	Matrix squaring criteria (DEFAULT 0.2)
SSTAR(n)	Resonance self shielding parameter $\sigma_{t,n}$* on page 44 of ABN
SUMPOP	Total fraction of the population that has been bypassed by the real matrix as it moves down in energy
SZERO(l)	Resonance self shielding parameter $\sigma_{o,\ell}$ on page 42 of ABN
TIM(n)*	Time at time step n (DEFAULT TIM(1)=0.0)
TIMD(n)	$\frac{1}{2}$(TIM(n) + TIM(n+1))
TIMWID*	Width of source pulse in time (DEFAULT 0.0)
TITLE(k)**	Title block storage
TOTL(n)	Total neutron loss rate at time n
U(i)*	Upper lethargy boundary for state i (DEFAULT U(1)=0.0)

V(i)	Lower velocity boundary for state i
VII(i)	Inverse of expectation on inverse scattering velocity (as used in calculation of B6)
ZA,ZB,ZC,ZD,ZE	Free parameters

APPENDIX D

LOGICAL CONTROL VARIABLES

Note: The integer variable L provides 30 locations for variables which control the sequence of operations performed by MOD-5. L(1) through L(20) are reserved for the operations listed below. L(21) through L(30) remain unassigned and are available for the programmer's use. In general, if L(n) = 1 the operation listed is carried out and if L(n) = 0 the operation is not carried out. Note that L(2) must always be defined to be 1 in the problem data set and this fact is used in READ (ftn 81,82) as a simple consistency check on the punched cards.

n	IF(L(n).EQ.1)
1	Set up run only, execution terminates after GENTIM
2	Problem initialization variable.
3	The real array is at the bottom of the virtual array. L(3) = 1 initially if the real and virtual arrays have the same dimension, i.e., if N = NVIR.
4	Define the state structure from E(NVM) upward. Default (0) value assumes state structure is to be defined from E(1) downward.
5	On-line plot of distributions in lethargy at time determined in AMULT.
6	Call STAWID to optimize state structure.
7	Call EXACT to calculate and print asymptotic time moments.
8	The source distribution in energy and the value of TIM(1) are specified in the input data set. If TIM(1) is not specified a default value of 0.0 seconds is assumed.
9	The source is to be monoenergetic (located in state 2) and uniformly distributed in time for an interval given by the input value of TIMWID.
10	There is fissionable material in the system
11	The source has a delta function distribution in time and energy. All neutrons start in state 1.
12	Inelastic scattering occurs. This variable must have an input value of 0. If one or more rows of the variable H has non-zero elements the program redefines L(12) = 1.
13	IF(L(5).EQ.1) plot distributions in lethargy as with L(5) = 1 but at closer intervals as defined in AMULT.
14	Punch output
15	Print DENS and SDENS

n	IF(L(n).EQ.1)
16	Print FISS, LEAK, CAPT, and TOTL
17	Print LEAK, CAPT, TOTL, DENS and SDENS
18	Write out detailed distributions (Interpolated distributions are always written)
19	Disregard instructions to terminate on ROWSUM error (WRITE2). XSECT defines L(19) = 1 when (n,2n) reactions take place.
20	Internally generated call for MODPLOT
21-30	Unassigned

APPENDIX E

DESCRIPTIONS OF SUBROUTINE FUNCTIONS

The MOD-5 package consists of a control program, MAIN, and 20 subroutines. MAIN is discussed in detail in Section I of this document. The subroutines are briefly described below, Equations referenced are to be found in the paper in APPENDIX A.

AMULT
1) Multiplies state vector into the transition matrix
2) Evaluates fission, capture, leakage and total loss rate at time NT; and density and slowing down density in bottom energy group.
3) Determines whether the lethargy dependent neutron density should be printed (punched). This is done if the current time step straddles a time $1x10^{-n}$, $2x10^{-n}$ or $5x10^{-n}$ seconds where n is an integer. If L(13) = 1 the density in lethargy is also printed at times near 1.5, 3, and $7x10^{-n}$ seconds.

EXACT
(OPTIONAL ROUTINE) Calculates asymptotic values of positive or negative moments of DENS to any order using expressions quoted in Williams, The Slowing Down and Thermalization of Neutrons, Chapter IX, Section II. First and second positive moments of SDENS are calculated using results of Pal and Nemeth, Nukleonik, 1, 5, 165 (1959).

GENRAT
Generates new rows of the transition matrix using Eqs. 14 and 15, after testing to see which rows satisfy Eq. 44 for the time step in use.

GENTIM
1) Determines the operating time step width from the values of OPCRIT and the state decay constant at the state with the greatest population.
2) Determines generating time and parameters each time a new real transition probability array is generated. See Eqs. 44-46.

GETIT
Called from READ to retrieve isotope numbers, names and masses, and the cross section set, from external files. Data sets are read sequentially and discarded until the desired set is found.

INCOND	1) Computes the average fission yield of neutrons in each state using fission yield parameters in Abagayan, et al. 2) Defines the source vector if it is to be a delta function or a fission spectrum. 3) Normalizes the source spectrum.
INTERP	Computes linearly interpolated values of time distributions (fission rate, etc.) on a uniform time mesh of up to 200 points. The first 20 points are spaced at $\frac{1}{4}$ the separation of the remaining points.
LIBRAR	This routine is intended for use with the ABN 26 group cross section library. 26 group microscopic cross sections are corrected for resonance self-shielding and converted to macroscopic cross sections. These are then used to define cross sections for each state with energy interval weighted averages for those states lying on a group boundary. The resonance self shielding coefficients are interpolated linearly if $\sigma_o < 1$ and logarithmically if $\sigma_o > 1$.
MODPLT	(OPTIONAL ROUTINE) Provides for on-line plotting of the lethargy dependent neutron density with no correction for non-uniformity of state widths.
MOMENT	1) Computes up to 21 moments of time distributions. 2) Computes exponential extrapolation corrections to the time distributions. 3) Computes multiplication constant. 4) Computes first energy moment of steady state core and leakage fluxes.
NORMAL	Normalizes time dependent distributions and fluxes to unit integral over time or lethargy.
OUTPUT	1) Computes relative standard deviation of time distributions. 2) Computes 26 group flux. 3) Prints or punches final output data.
PARAM	1) Defines lethargy, energy, and velocity values for state boundaries; and lethargy, energy and velocity widths of each state. May start from pre-determined lethargies of state boundaries or lethargy widths of states.

2) Evaluates NG(i) to define group to which state i belongs.
3) Evaluates NNG(k) to specify index of lowest energy state lying completely in group k.

READ

1) Initializes parameters ND, NOMAX, MAXT, MAXR, MAXV, NGR, and NTITLE which specify dimensionality of the common block and the number of isotopes in the external file.
2) Assigns DEFAULT values.
3) Re-orders isotopes in ascending mass order (Exception: when present, hydrogen is always listed last by READ).
4) Reads all card input data.
5) Provides parameter and vector initial values.

SQUARE

Squares the transition matrix. Elements of the newly squared matrix are stored in their transposed position (lower triangular) in the matrix until the squaring process has been completed. The elements are then transposed to their normal position. SQUARE provides two squaring routines, one for a matrix in which not all of the rows have been defined, and one for a fully defined matrix.

STAWID

(OPTIONAL ROUTINE) This routine is used to adjust the lethargy width of the states to obtain optimal treatment of elastic scattering. (see Appendix A, pp. 45-46). To employ this routine the user must define NSCAT, the number of lower energy states into which neutrons are allowed to scatter from a given state. STAWID automatically calculates an initial estimate of the desired lethargy width and then iterates on this to refine the value.

TRAN

This routine computes the transfer coefficient matrix (transition probabilities are assembled from these in GENRAT). The model assumes constant cross sections across each state. The transfer coefficient array is computed in transposed form so it may be stored in the lower triangular portion of the matrix P(i,j). Transition probabilities are stored in the upper triangular and diagonal elements of the array. Inter-state inelastic scattering transfer probabilities are derived from the inelastic transfer matrices of the 26 group cross section set using energy interval weighting.

WRITE1

Lists input and computed data for problem description. If common block is altered such that ND (maximum number of isotopes in system) exceeds 5 this subroutine will have to be updated.

WRITE2	Lists state structure parameters and tests the transfer coefficient array to see that probabilities along a row (column in transposed form) sum to unity.
XSECT	1) Macroscopic cross sections are divided by the total cross section to normalize them for use in defining transfer coefficients. 2) The inelastic scattering array is tested for (n,2n) reactions. 3) The inelastic scattering array is normalized.

APPENDIX H

EXAMPLES OF OUTPUT FROM MOD-5

Note: The listings that follow are incomplete and are intended only to provide verification that the sample data decks have been properly executed.

STATE WIDTH OPTIMIZATION DATA

THE INITIAL LETHARGY DECREMENT (LOG10) IS 0.96645E-01
1 STATE(S) PER SCATTERING INTERVAL
THE CONVERGENCE CRITERIA IS 0.00001

AT ITERATION NUMBER 1, THE ERROR IS -0.02748, RR(2) = 1.49646, AND THE NEW LETHARGY WIDTH IS 0.10468E 00

AT ITERATION NUMBER 2, THE ERROR IS -0.00554, RR(2) = 1.54896, AND THE NEW LETHARGY WIDTH IS 0.10628E 00

AT ITERATION NUMBER 3, THE ERROR IS -0.00116, RR(2) = 1.55972, AND THE NEW LETHARGY WIDTH IS 0.10662E 00

AT ITERATION NUMBER 4, THE ERROR IS -0.00025, RR(2) = 1.56198, AND THE NEW LETHARGY WIDTH IS 0.10669E 00

AT ITERATION NUMBER 5, THE ERROR IS -0.00005, RR(2) = 1.56246, AND THE NEW LETHARGY WIDTH IS 0.10671E 00

AT ITERATION NUMBER 6, THE ERROR IS -0.00001, RR(2) = 1.56256, AND THE NEW LETHARGY WIDTH IS 0.10671E 00

AT ITERATION NUMBER 7, THE ERROR IS -0.00000, RR(2) = 1.56258, AND THE NEW LETHARGY WIDTH IS 0.10671E 00

---- A MOD5 CALCULATON ----

EXAMPLE NUMBER 1
EVALUATION OF ASYMPTOTIC SOLUTION TO SLOWING DOWN EQUATION.
INFINITE GRAPHITE MODERATOR. DELTA SOURCE IN TIME AND ENERGY.

THE CENTRAL CORE FLUX-AVERAGED ENERGY IS 1.297E 04 EV.
THE LEAKAGE FLUX-AVERAGED ENERGY IS 0.0 EV.

AT 6.215E-05 SECONDS--
0.0 PERCENT OF THE NEUTRONS HAVE SUFFERED NON-FISSION CAPTURE,
0.0 PERCENT OF THE NEUTRONS HAVE LEAKED FROM THE SYSTEM,
0.0 PERCENT OF THE NEUTRONS HAVE CAUSED FISSION,
99.647 PERCENT OF THE NEUTRONS HAVE ENERGY BELOW 1.00E 00 EV,
0.001 PERCENT ARE STILL SLOWING DOWN,
0.352 PERCENT ARE LOST FROM THE SYSTEM, AND
0.0 PERCENT HAVE BEEN BYPASSED BY THE ARRAY.

---- A MOD5 CALCULATON ----

EXAMPLE NUMBER 2
STUDY OF SLOWING DOWN OF NEUTRONS FROM A 0.5 MICROSECOND, 2.46 MEV PULSED SOURCE (D,D). DEMONSTRATES TRAVELING ARRAY.

THE CENTRAL CORE FLUX-AVERAGED ENERGY IS 2.911E 05 EV.
THE LEAKAGE FLUX-AVERAGED ENERGY IS 0.0 EV.

AT 9.655E-05 SECONDS--
0.0 PERCENT OF THE NEUTRONS HAVE SUFFERED NON-FISSION CAPTURE,
0.0 PERCENT OF THE NEUTRONS HAVE LEAKED FROM THE SYSTEM,
0.0 PERCENT OF THE NEUTRONS HAVE CAUSED FISSION,
97.965 PERCENT OF THE NEUTRONS HAVE ENERGY BELOW 1.01E 00 EV,
0.000 PERCENT ARE STILL SLOWING DOWN,
2.035 PERCENT ARE LOST FROM THE SYSTEM, AND
0.113 PERCENT HAVE BEEN BYPASSED BY THE ARRAY.

---- A MODS CALCULATON ----

EXAMPLE NUMBER 3
STUDY OF SLOWING DOWN SPECTRA IN REPRESENTATIVE FAST MULTIPLYING ASSEMBLY. FISSION SOURCE - DELTA FUNCTION IN TIME.

THE MULTIPLICATION CONSTANT OF THE SYSTEM IS
****
* K = 0.981699E 00 *
****

ESTIMATE OF K FROM TRUNCATED DISTRIBUTION---- 0.969340

THE CENTRAL CORE FLUX-AVERAGED ENERGY IS 8.912E 05 EV.
THE LEAKAGE FLUX-AVERAGED ENERGY IS 1.454E 06 EV.

AT 3.113E-07 SECONDS--
9.899 PERCENT OF THE NEUTRONS HAVE SUFFERED NON-FISSION CAPTURE,
51.251 PERCENT OF THE NEUTRONS HAVE LEAKED FROM THE SYSTEM,
37.870 PERCENT OF THE NEUTRONS HAVE CAUSED FISSION,
0.002 PERCENT OF THE NEUTRONS HAVE ENERGY BELOW 1.18E 01 EV,
1.183 PERCENT ARE STILL SLOWING DOWN,
-0.125 PERCENT ARE LOST FROM THE SYSTEM, AND
0.004 PERCENT HAVE BEEN BYPASSED BY THE ARRAY.

13. ABSTRACT

This document provides users' information for a computer code, MOD-5, which calculates the time and energy dependent evolution of the neutron density in homogeneous media following initiation of a pulsed neutron source of arbitrary energy distribution. The code is based on a discrete stochastic model of the neutron slowing down process developed by the author. Copies of the code and associated computer software are available through the Argonne Code Center, Argonne National Laboratory, 9700 South Cass Avenue, Argonne, Illinois 60439.
